Sales & Order Overview

Olist Brazilian E-Commerce | Power BI Report

Francesco Di Stasio

Introduction

This report summarizes sales activity, geographic concentration, product-category performance and shipping charges in the public Olist dataset. Python was used for preparation and integration; Power BI provides the data model, DAX measures and report visuals. Sales measures include only orders whose recorded status is `delivered`. The order-status chart includes all recorded statuses within the selected purchase period.

Data model and metric definitions

The model connects `Orders` (one row per order) to `OrderItems` (one row per order item) through an active, single-direction, one-to-many relationship on `order_id`. Sales and freight are summed from item-level fields; distinct order counts prevent multiple items from inflating the denominator.

Sales Value is the sum of item prices, excluding freight. **Average Order Value** divides this amount by distinct delivered orders with recorded items. **Items Sold** counts item rows. **Total Freight** represents recorded customer freight charges, not verified carrier costs. **Freight-to-Sales Ratio** is total freight divided by sales value. None of these measures represents profit or Olist's net revenue.

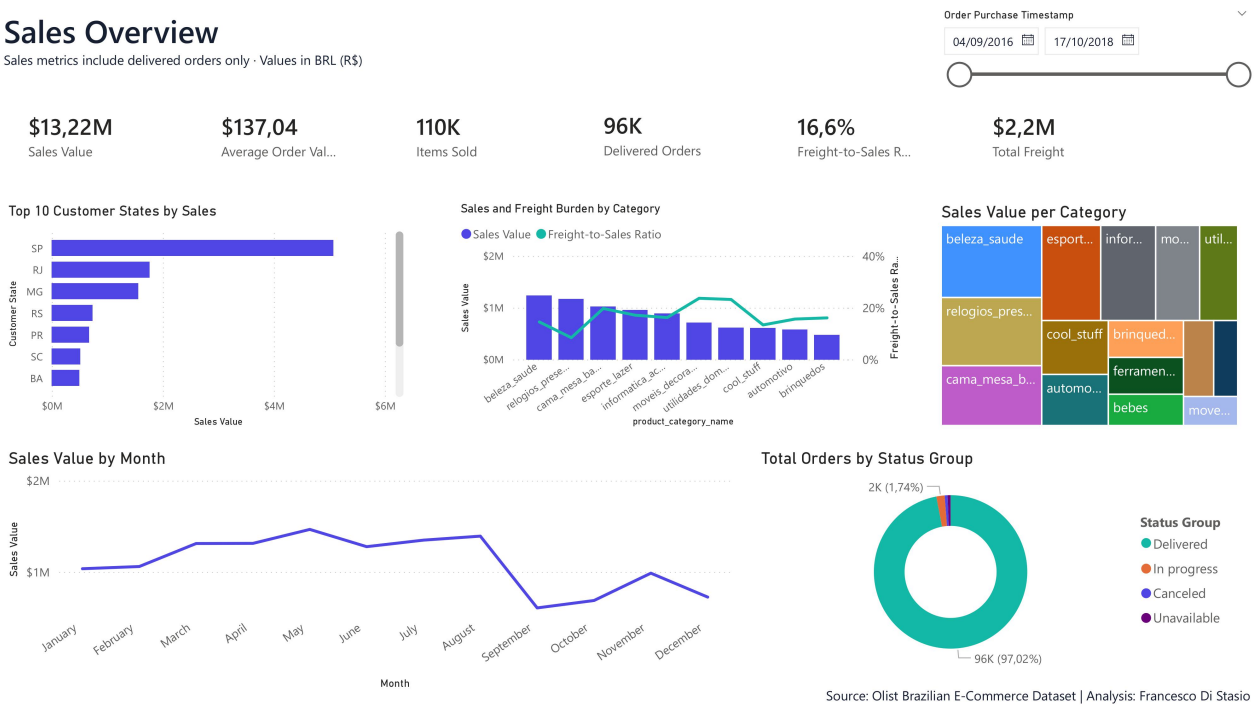

Figure 1. Sales overview for the displayed purchase-date selection.

Notes

The screenshot shows approximately R$13.22 million in item sales, an average order value of R$137.04 and a freight-to-sales ratio of 16.6%. Card values are rounded and depend on the date selection. Status reflects a historical snapshot; "In progress" does not imply current activity. A January–December axis pools years unless the underlying field includes year and month; use a continuous year-month axis for chronological trends.

DAX measures

These measures reproduce the six KPI cards and the all-status order count. Monetary measures use BRL; the freight ratio uses percentage formatting. Table and column names match the Power BI model.

```
Sales Value =
CALCULATE(
    SUM(OrderItems[price]),
    Orders[order_status] = "delivered"
)

Delivered Orders =
CALCULATE(
    DISTINCTCOUNT(OrderItems[order_id]),
    Orders[order_status] = "delivered"
)

Items Sold =
CALCULATE(
    COUNTROWS(OrderItems),
    Orders[order_status] = "delivered"
)

Average Order Value =
DIVIDE([Sales Value], [Delivered Orders])

Total Freight =
CALCULATE(
    SUM(OrderItems[freight_value]),
    Orders[order_status] = "delivered"
)

Freight-to-Sales Ratio =
DIVIDE([Total Freight], [Sales Value])

Total Orders =
DISTINCTCOUNT(Orders[order_id])
```

Calculated columns

Create `Status Group` in `Orders` for the donut chart. For a chronological monthly line, create `Purchase Month`, format it as `MMM yyyy`, and use the date field rather than a month-name grouping.

```
Status Group =
SWITCH(
    Orders[order_status],
    "delivered", "Delivered",
    "canceled", "Canceled",
    "unavailable", "Unavailable",
    "In progress"
)

Purchase Month =
DATE(
    YEAR(Orders[order_purchase_timestamp]),
    MONTH(Orders[order_purchase_timestamp]),
    1
)
```
